- Software for which extra effort is expended in order to make changes.
- The system is hard to change because every change forces many other changes to other parts of the system.

       #define ADC DATA SHIFT (2)
 5
       #define ADC_SIGN_CONVERSION (1)

#### Refactor to reduce rigidity

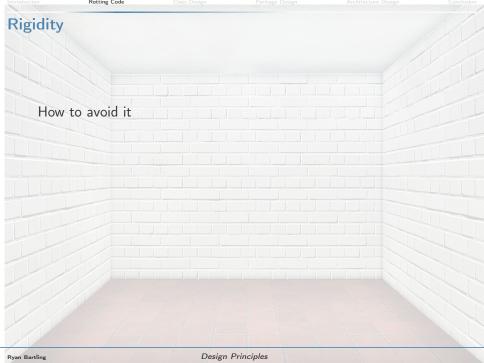

```
#include <stdint.h>
 2
 3
      #define ADC_BITS (14)
      #define ADC_DATA_SHIFT (2)
      #define ADC_SIGN_CONVERSION (1)

 8
9
      #define LFSR_LENGTH (4)
10
      #define LFSR_REPEATS (2)
11
      #define CORRELATED_BITS (RAW_ADC_BITS + LFSR_LENGTH + log_2(LFSR_REPEATS))
12
      typedef_min_int(rpo_correlated_int_t, CORRELATED_BITS);
```

How to avoid it

- Write DRY code (Don't repeat yourself)
- Define the code in logical pieces. Set boundaries and responsibilities.

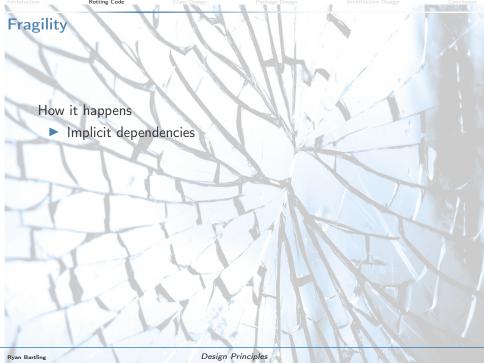

## **Fragility**

- ► Easily broken or destroyed
- Software for which extra risk is incurred in order to make changes.
- Changes cause the system to break in places that have no conceptual relationship to the part that was changed.

- ► Implicit dependencies
- Unmanaged shared resources
- Relying on implementation details
- Relying upon side effects of operations
- Reaching past abstraction layers

- Unmanaged complexity

# **Fragility**

Changing the sensor to use mode 1...

...Breaks the sd card (when sensor is initialized after the sd card)

# **Fragility**

We can fix it with dynamic resource allocation...

```
void
      sdcard_init(void) {
          if(spi_success != spi_acquire(mode_0, card_cs_pin)) { return; }
          fat init():
 5
          spi_release();
 6
 7
 8
      void
 9
      sensor_init(void) {
10
          if(spi_success != spi_acquire(mode_1, sensor_cs_pin)) { return; }
11
          spi_write(SENSOR_CONFIGURATION, sensor_cs_pin);
12
          spi_release();
13
```

If multi threaded, we could spin lock...

```
void
      sdcard_init(void) {
          while(spi_success != spi_acquire(mode_0, card_cs_pin)) {}
          fat_init();
 4
 5
          spi_release();
 6
 7
 8
      void
 9
      sensor_init(void) {
10
          while(spi_success != spi_acquire(mode_1, sensor_cs_pin)) {}
11
          spi_write(SENSOR_CONFIGURATION, sensor_cs_pin);
12
          spi_release();
13
```

### We could also have a common allocation and assert correctness...

```
void
       sys_init(void) {
           spi_init(mode_0);
 5
 6
      void
      sdcard init(void) {
           assert(mode_0 == spi_mode_get() && "Wrong spi mode for sdcard");
           fat_init();
10
11
12
      void
13
      sensor_init(void) {
14
           assert(mode_0 == spi_mode_get() && "Wrong spi mode for sensor");
15
           spi_write(SENSOR_CONFIGURATION, sensor_cs_pin);
16
```

#### Viscous Policies

- Management steps in to avoid the issues above
- "We cannot afford to have anyone touch the Fobnicator stack, because too many things depend upon it"
- Policies can remain long after the original problem was solved.
- Process can also result in viscocity. If a more correct soluton triggers a heavier round of reviews, the incorrect solution that can get by with less review and documentation will be favored by the developers. E.g. Creating a new module requires upfront design review. Adding the same code inside an existing module requires only the normal code review.
